```

How to train:

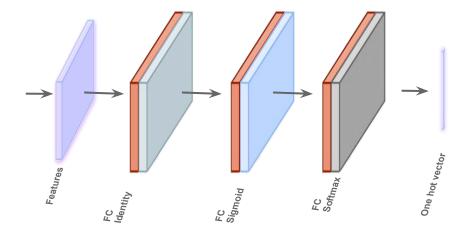

\$ python3 train.py train "data/train.csv"

How to predict:

\$ python3 train.py predict "data/test.csv" models_/541.ckpt

```

Architecture

Explanation

Features extraction & Engineering:

The chosen features are: Sold Price, Price, Area Name, Condition, Size Condition and Area name were simply converted into numbers as follows:

```
condition = {"Fair": -1, "Good": 2, "Like New": 3}
area = {"aaa": 1,"bbb": 2,"ccc": 3,"ddd": 4,"eee": 5,"fff": -6,"ggg": -7,"hhh": -8,"jjj": -9,"kkk": -10}
units = line.split(",")
X = [float(units[2]) / 1000.0,float(units[3]) / 1000.0, float(area[units[4]]), float(condition[units[5]]), -float(units[6])]
```

Dataset is so small (~ 700 points), the first implementation suffered from overfitting, I solved the problem by augmenting the data 3 times.

Model training:

Weights were initialized by Xavier Initialization Cross Entropy with logit was chosen as a loss function Adam optimizer with a batch size of 500 was used for training. Data were shuffled every 10 epochs.

Model Evaluation:

The augmented dataset was divided into 70% for training, and 30% for validation. The accuracy and losses are shown below.

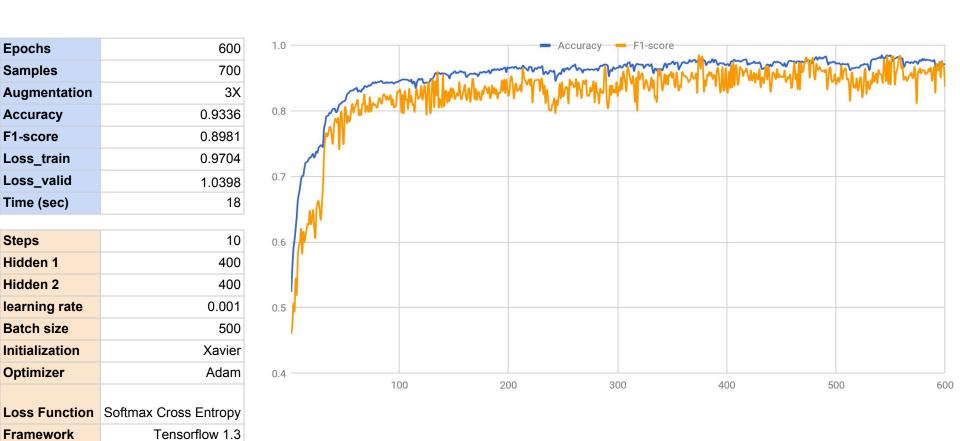

Evaluation

Epochs	60
Samples	70
Augmentation	3
Accuracy	0.933
F1-score	0.898
Loss_train	0.970
